Abstract
A survey on a series of issues regarding the student's perception of the academic environment was conducted at Technical University of Cluj-Napoca. A sample of 403 students was included into analysis using a stratified random sampling procedure by year of study, faculty, and specialty. The academic community involvement of four main actors represented by academic staff, faculty staff, teachers, and administrative personal was analyzed in view of student’s perception. The results of the study showed that the students perceive three degrees of academic community involvement (academic staff and administrative personal, faculty staff, teachers and students). This perception is related with the distance between observer and the observable.

Keywords: Student t test, Jarque-Bera test, academic community, involvement degree, perception, expectation

Introduction
Students, as individuals, know their own attitudes, emotions, and other internal states partially by inferring between observations of their own behavior and/or circumstances in which this behavior occurs (Bem, 1967). They may infer some of their own traits by observing others with whom they feel a sense of merged identity (Goldstein and Cialdini, 2007). These demonstrate that the student’s view of himself/herself is in direct relation with the observation of how others within their close environment behave.

Motivation to learn is a student’s desire or willingness to engage and persist in academic activities in school (Brophy, 1986) even they are under a high risk do not take school or their studies seriously (Steinberg, 1996).

Under this auspices knowing more about the students outlook regarding of the involvement of the academic community is a key element for defining the objectives of a strategic management in education.

The higher education institutions are confronted with an explosion of control measures, steering mechanisms and increasing accountability pressures (Pollitt, 1993) compared to the autonomy era (Hood, 1995). Thus, New Public Management advocates the adoption of private management instruments within public sector organizations in order to increase efficiency, effectiveness and quality (Hood, 1991; Bach, 2000; Ferlie and Steane, 2002).

Cothran and Ennis highlight that very few information are known in regards of what students think about schooling and engagement (Cothran and Ennis, 2000). The student perspective is essential and their opinion must be listening in order to increase the likelihood of their own educational engagement in regards for a meaningful educational reform to take shape.

The aim of our research was to identify and assess the perception of students from the Technical University of Cluj-Napoca, Romania on degree of academic community involvement in the academic.
Material and Method

Technical University of Cluj-Napoca is located in Cluj County, approximately in the middle of Transilvania region. It is the second university as size from six state universities in the city and serves approximately 13000 students in nine faculties.

During the first semester of 2008/2009 academic year a survey was conducted. A questionnaire with 30 questions was applied to the students from first to last (5-th) year of the first cycle in higher education.

A stratified random sampling method was applied in order to construct the sample of students included into analysis. Thus, the population of the random sampling was constituted from smallest study formations from all faculties and years of study (subgroups), varying from 7 to 21 students, in number of about 1000. Random sampling was applied on these subgroups, and 30 subgroups were selected to be included in the survey. The questionnaire was distributed to the selected groups in order to be field freely. From a number of 452 enrolled students a number of 437 attended at the moment of the survey and 403 accepted to participate to the survey.

One of the survey questions (6th question) was How you appreciate the involvement degree of the following actors of the academic community in the academic life?: a. Academic Staff; b. Faculty Staff; c. Teachers; d. Administrative Personal; f. Students. The student’s were asked to quantify the involvement in the academic life of each class of actors on a None-Small-Medium-High-Highest scale (see Table 1).

The degrees of involvement in the academic life quantified by students according to the investigated communities were structured into a contingency table (see Table 1) in order to answer to two main issues. First issue regards the research assumptions. The obvious hypothesis is that it should be an association between the involvement and the community through student’s perspective. In the same time, the alternative hypothesis may give the answer if the involvement (analyzed as categorical variable) has the same distribution in all five academic communities proposed for investigation (academic staff; faculty staff; teachers; administrative personal; and students). Second issue regards the distribution law of the involvement degree, seen as a continuous variable of an unknown (and to be determined) mean and variance. In order to deal with the second issue, a scale for the involvement categorical variable was assigned: 0 = None; 1 = Small; 2 = Medium; 3 = High; 4 = Highest. Moreover, a more accurate approach is to use an unknown expectation for the highest category.

Results and Discussion

A total number of 403 students complete the questionnaire. The frequency distribution of the answers according to students’ faculty is as follows: 25 from Constructions; 87 from Automation and Computer Science; 95 from Building Services; 35 from Machine Building; 45 from Electronics Telecommunications and Inform; 29 from Electrical Engineering; 14 from Installations in Constructions; 53 from Civil Engineering and 20 from Faculty of Materials Science and Engineering.

Almost 95% answers were valid from the total number of 403 questionnaires. The distribution expressed as absolute frequencies of the degree of involvement in academic life of the studied populations are presented in Table 1. There are no observed biases, largest percent being for faculty staff (98.8%) and smallest percent being for academic staff (96.5%).

In order to perform the analysis of association between the involvement and the community through student’s perspective, the Chi Square test were applied on the data from Table 1. The observed involvement (as categorical variable) of each community sub-population in the view of student’s perception and the community were used in this analysis. Under hypothesis of homogeneity/independence the expected values ($E_{i,j}$, $1 \leq i, j \leq 5$) for the observed data presented in Table 1 are given by Eq(1) (Fisher, 1925).

$$E_{i,j} = \frac{\left( \sum_{k=1}^{5} O_{i,k} \right) \left( \sum_{k=1}^{5} O_{k,j} \right)}{\sum_{i=1}^{5} \sum_{j=1}^{5} O_{i,j}}$$ (1)

where $O_{i,j}$ are the entries from Table 1 ($i =$ encodes the category of academic community and $j =$ encodes the involvement categories).

The result of the Chi Square statistic ($X^2$) is given in Table 2. This result showed that there is a relationship between the academic role and student’s opinions on degree of involvement; the association is assured on every academic role (Table 2, $p_{X^2}$ column).

$p_{X^2}(ΣX^2,df,2)$: the probability from Chi Square distribution to observe a departure from agreement larger than observed one ($ΣX^2$)

df = 4 for every role ($Σ$) and df = 16 for entire community ($ΣΣ$)

A comparison between academic communities regarding the perception of their involvement degree in the views of students’ perception was considered suitable and was conducted (Fisher, 1925). The assumption of binomial distribution of perception should be verified in order to compare the perceptions. The true proportions into the populations was be obtained using the uniform category values (0 = None; 1 = Small; 2 = Medium; 3 = High; 4 = Highest) and a binomial approximation of the distribution (see Table 3).

$p$: True proportion in population; $p_{X^2}(ΣX^2,df,2)$: the probability from Chi Square distribution to observe a departure from agreement larger than observed one

The results presented in Table 3 revealed that by using a uniform scale for category values we are in error, being hard to reject binomial or normal assumption for the student’s perceptions. Thus, a different approach is necessary to be conducted. The natural way is to assume that the last category (Highest) may have different perception (and thus different category value), which should be assigned with the expectation of involvement.
Moreover, this expectation is supposed to be different from one population to another. Therefore, the mean and the expectation under assumption that the populations of involvement are normal distributed were subject to the analysis.

The Jarque-Bera’s test (Jarque and Bera, 1981) was used as option under normality assumption to find the best values for the means ($\mu_i$, i = 0 - academic staff, i = 1 - faculty staff, i = 2 - teachers, i = 3 - administrative personal, and i = 4 - students).

Under the assumption that the categories have the values 0 = None; 1 = Small; 2 = Medium; 3 = High; $E_i$ = Highest) the formulas for population skewness ($Sk_i$) and kurtosis ($Ku_i$) became as were presented in Eq(2) and Eq(3) (where $n_i$ = number of observations in each sample).

$$Sk_i = \frac{n_i\sqrt{n_i-1}}{n_i-2} \left[ \frac{O_{i,4}(E_i - \mu_i)^3 + \sum_{j=0}^{3} O_{i,j}(j - \mu_i)^3}{O_{i,4}(E_i - \mu_i)^2 + \sum_{j=0}^{3} O_{i,j}(j - \mu_i)^2} \right]^{3/2}$$  \hspace{1cm} (2)

$$Ku_i = \frac{(n_i+1)n_i(n_i-1)}{(n_i-2)(n_i-3)} \left[ \frac{O_{i,4}(E_i - \mu_i)^4 + \sum_{j=0}^{3} O_{i,j}(j - \mu_i)^4}{O_{i,4}(E_i - \mu_i)^2 + \sum_{j=0}^{3} O_{i,j}(j - \mu_i)^2} \right]^{3} \left( \frac{3(n_i-1)}{n_i(n_i+1)} \right)$$  \hspace{1cm} (3)

The formula of Jarque-Bera’s statistic for the populations is given in Eq(4).

$$JB_i = \frac{n_i}{6} \left( Sk_i^2 + Ku_i^2 / 4 \right)$$  \hspace{1cm} (4)

and it depends on $E_i$ (populations expectances) and $\mu_i$ (populations mean).

It is well known that JB statistic had a Chi Square distribution with two degrees of freedom. In order to obtain the values for $E_i$ and $\mu_i$ the normality assumption in which both $Sk_i$ and $Ku_i$ converges to 0 was used. Therefore, the JB should be minimized:

$$JB_i(\mu_i,E_i) = \text{min.} \quad \Leftrightarrow \frac{\partial JB_i(\mu_i,E_i)}{\partial \mu_i} = 0 = \frac{\partial JB_i(\mu_i,E_i)}{\partial E_i}$$  \hspace{1cm} (5)

The Eq(5) can be solved analytically or numerically by using a math program. We solved it numerically and the following values were obtained:

$$JB_0 = \text{min.} \quad \Rightarrow \quad JB_0 = 1.5 \cdot 10^{-3}; \quad \mu_0 = 1.75; \quad E_0 = 4.32$$  \hspace{1cm} (6)

$$JB_1 = \text{min.} \quad \Rightarrow \quad JB_1 = 4.7 \cdot 10^{-4}; \quad \mu_1 = 2.02; \quad E_1 = 4.44$$  \hspace{1cm} (7)

$$JB_2 = \text{min.} \quad \Rightarrow \quad JB_2 = 5.8 \cdot 10^{-3}; \quad \mu_2 = 2.30; \quad E_2 = 4.54$$  \hspace{1cm} (8)

$$JB_3 = \text{min.} \quad \Rightarrow \quad JB_3 = 3.1 \cdot 10^{-3}; \quad \mu_3 = 1.67; \quad E_3 = 4.48$$  \hspace{1cm} (9)

$$JB_4 = \text{min.} \quad \Rightarrow \quad JB_4 = 5.593; \quad \mu_4 = 2.48; \quad E_4 = 4.45$$  \hspace{1cm} (10)

An immediate remark comes form equations (6-10): the Jarque-Bera’s statistic for the perception of the student’s involvement is significantly biased than the others (from Chi Square distribution we may find that only about 6% of observations can be worst than that). This remark can be assumed to be true since measuring by themselves is a source of bias. The second remark is that all other JB’s statistic are very good, the models (6)-(9) being improvements of the models presented in Table 3 (for equations (6)-(9) the highest probability for being in error is for Eq(8) and it is smaller than 3‰).

According to the results (Eq(6)-(10)) the greatest involvement expectation of students is for teachers ($E_2 = 4.54$) and the lowest expectation is for academic staff ($E_2 = 4.32$).

The obtained values of means and expectation were used in order to perform a mean comparison test. The Student t test (Student, 1908), modified for different variances and sample sizes (Welch, 1947) was applied (see eq(11), where $s_i$ should be expressed as distance from known means ($\mu$) as in Eq(12)).

\[ t_{i,j} = \frac{\mu_i - \mu_j}{\sqrt{\frac{s_i^2}{n_i} + \frac{s_j^2}{n_j}}}, \quad \text{df}_{i,j} = \frac{\left(\frac{s_i^2}{n_i} + \frac{s_j^2}{n_j}\right)^2}{(n_i - 1) + \left(\frac{s_i^2}{n_i}\right)^2/(n_i - 1)} \]  

\[ s_i^2 = O_{i,4}(E_i - \mu_i)^2 + \sum_{j=0}^{3} O_{i,j} (j - \mu_i)^2 \]  

Table 4 cumulates the results for means (\(\mu_i\)), expectances (\(E_i\)) and variances (\(s_i^2\)).

Aca: Academic staff; Fac: Faculty staff; Std: Students
Cdi: Teachers; Adm: Administrative personal

Table 5 showed that with a 5% risk of error we cannot reject the hypothesis that the mean of involvement in academic life for academic staff is the same with the mean of involvement in academic life for administrative personal (the probability of observing better agreement is 79%). With a 1% risk of error we cannot reject the hypothesis that the mean of involvement in academic life for teachers is the same with the mean of involvement in academic life for students (the probability of observing better agreement is 79%) though student’s perception.

Using the values from Table 4, the density probability functions of student’s perception of involvement for the different academic communities was graphically presented in Figure 1.
Figure 1. Density probability functions (PDFs) for student’s perception of academic life
involvement of different academic communities (Aca: Academic staff, Fac: Faculty staff, Adm:
Administrative personal, Cdi: Teachers, Std: Students)

Conclusions
The results obtained in our study revealed that students have different expectations for involvement
in academic life for different academic communities. The greatest expectation is from teachers
(expectance of 4.54), followed by administrative personal (expectance of 4.48), the academic
communities with which are supposed to be in direct contact often then with the others. The lowest
expectation comes from academic staff (expectance of 4.32).

By taking variance as a measure of diversity, the less flexible about the involvement in academic
life are seen the administrative personal (variance of 0.74) followed by academic and faculty staffs
(variance of 0.86 and 0.84, respectively), and more flexible are seen themselves (variance of 1.27).

By taking the mean as measure for degree of involvement, the lowest involvement are seen coming
from administrative personal (mean of 1.67) hard to differentiate from the involvement coming
from academic staff (mean of 1.75, 21% overlapping) and the highest involvement are seen coming
from teachers (of 2.30) and of course by themselves (of 2.48).
